## Zusammenfassung

Die Pulsation eines Sterns enthält Information über die physikalischen Bedingungen in seinen tieferen Schichten. Druckmoden (p Moden) laufen durch seine äußeren Schichten, während sich Schwerkraftmoden (g Moden) tief im Inneren der Sterne ausbreiten. Daher sind g Moden besonders interessant, können jedoch nur bei bestimmten Sternen beobachtet werden.  $\gamma$  Dor Sterne oder langsam pulsierende B Sterne (SPB) sind beispielsweise solche Sterne, bei denen die g Moden hohe Amplituden zeigen und daher leicht beobachtet werden können. Hybridsterne (Mischformen), welche gleichzeitig in p und g Moden pulsieren, eignen sich besonders für Asteroseismologie.

Die CoRoT Langzeitbeobachtungen (Long Runs) bieten eine großartige Gelegenheit eine große Stichprobe solcher Sterne zu analysieren. Diese Daten wurden unter homogenen Beobachtungsbedingungen, ohne signifikante Datenlücken und für eine Dauer von ca. 150 Tagen gewonnen, was mit bodengebundenen Instrumenten praktisch nicht möglich ist. Da die Weltraumteleskope die Szintillation der Erdatmosphäre umgehen, ermöglichen sie stellare Oszillation auf unter tausendstel Magnituden zu finden, sogar für 15 mag schwache Sterne. Die photometrischen Daten werden ergänzt durch AAOmega Klassifikationsspektren, die die Bestimmung der Effektivtemperatur und der Schwerebeschleunigung an der Oberfläche erlauben.

Mit diesen Daten wurde ein statistischer Ansatz verfolgt um das Pulsationsverhalten der  $\gamma$  Dor und  $\gamma$  Dor –  $\delta$  Sct Hybridsterne zu beschreiben. Eine Perioden – Temperatur-Beziehung wurde für  $\gamma$  Dor und  $\delta$  Sct Sterne gefunden, nicht aber für Hybridsterne, wenn man nur ihre stärksten Pulsationsmoden (g bzw p Moden) berücksichtigt. Hybridsterne verhalten sich anders im Bereich der g Moden als  $\gamma$  Dor Sterne, was die ernste Frage nach einer adequaten Definition von Hybridstern aufwirft. Der Anregungsmechanismus der g Moden sollte bei Sternen heisser als die  $\gamma$  Dor Sterne nicht mehr funktionieren, trotzdem wurden g Moden bei Hybridsternen gefunden, die heisser sind als  $\gamma$  Dor Sterne. Das weist auf einen anderen Anregungsmechanismus hin, der g Moden bei diesen Hybridsternen und  $\gamma$  Dor Kandidaten anregt, die

---

jenseits der blauen Grenze des  $\gamma$  Dor Instabilitätsstreifens liegen.

Der Vergleich der Pulsationsperioden der Hybridsterne zu jenen der  $\delta$  Sct Sternen zeigt ebenfalls eine signifikante Abweichung. Da die Hybridsterne keine Temperatur – Perioden-Beziehung zeigen, wird nahegelegt, dass es sich bei Hybridsternen um eine eigenständige Klasse von pulsierenden Sternen handelt. Da jedoch die Lage im Hertzsprung-Russell-Diagramm mit der der  $\delta$  Sct übereinstimmt, wird erwartet dass der innere Aufbau dieser beiden Gruppen gleich ist.

Die Untersuchung auf konstanten Periodenabstand der g Moden der  $\gamma$  Dor Sterne ergibt allgemein zu niedrige Werte, als die von der Theorie erwartet werden. Ich finde Periodenabstände, die mit  $\ell > 3$  Moden erklärt werden können. Solche Moden aber unterliegen bereits Auslöschungseffekten und sind kaum nachweisbar sogar mit hochgenauen Photometer wie CoRoT eines ist. Jedoch ist zu beachten, dass mit meinen Daten keine Modenidentifikation durchgeführt werden kann, daher besteht die Möglichkeit, dass Moden mit verschiedenen  $\ell$  diese Periodenabstände vortäuschen.

Um einen möglichen Zusammenhang des Hybridphänomens mit einem Elementhäufigkeits-muster zu untersuchen, wurde für zwei Hybridsterne eine detaillierte Häufigkeitsanalyse durchgeführt. Diese Analyse ergibt keinen Zusammenhang mit dem Auftreten von Hybridpulsation mit chemischen Häufigkeitsmustern (z.B. Am), und pekuläre chemische Oberflächenhäufigkeiten und Pulsation schließen sich nicht gegenseitig aus.

# Appendix G

## Abstract

Stellar pulsation carries information on the physical condition within the star. While pressure modes (p modes) probe the outer layers of a star, gravity modes (g modes) penetrate deep into the radiative zone and thus carry valuable information on the physical conditions there.  $\gamma$  Dor stars are stars that pulsate in such modes, apart from white dwarfs and slowly pulsating B (SPB) stars. Therefore, these stars are important test benches for stellar evolution and pulsation theory.  $\delta$  Sct -  $\gamma$  Dor hybrids are stars that pulsate like  $\gamma$  Dor stars with g modes but also with p modes as the  $\delta$  Sct stars do. This makes them even more suited for asteroseismology.

The CoRoT long runs offer a great opportunity to analyse a large sample of stars observed homogeneously, uninterrupted and long time base of  $\approx 150$  days, which is practically unachievable with ground based observation. Since space missions avoid the scintillation caused by the Earth's atmosphere, they allow to detect stellar oscillations on a sub-millimagnitude level even for stars as faint as 15th magnitude. The photometric data is supplemented by AAOmega classification spectroscopy, allowing to determine effective temperatures and surface gravity.

With these data a statistical approach was adopted to describe the pulsation behaviour  $\gamma$  Dor and  $\delta$  Sct -  $\gamma$  Dor hybrid stars. A temperature – period relation was found for  $\gamma$  Dor and  $\delta$  Sct stars, but none for  $\delta$  Sct -  $\gamma$  Dor hybrid stars, when considering their strongest g mode or p mode, respectively. The instability domain of hybrid stars is equal to that of  $\delta$  Sct stars and is not confined to the overlapping region of the  $\delta$  Sct and  $\gamma$  Dor IS in the Hertzsprung-Russell diagram. Hybrid stars behave differently in the g mode regime than  $\gamma$  Dor stars, which poses a serious question on how to define properly a  $\delta$  Sct -  $\gamma$  Dor hybrid. The convective flux blocking mechanism is supposed to work for stars in the  $\gamma$  Dor regime, but not for stars hotter than the blue border of the  $\gamma$  Dor instability strip, as the hybrids are. Thus, my finding is an evidence for another driving mechanism, which excites the observed g modes of hybrid stars and  $\gamma$  Dor candidates beyond the hot border of the  $\gamma$  Dor instability strip.

---

A comparison to the pulsation periods of  $\delta$  Sct stars show a discrepancy for p modes as well. For  $\delta$  Sct stars a temperature – period relation was found but none for hybrids. This finding suggests that the hybrid stars form a different class of pulsating stars and are not merely a mixture of  $\delta$  Sct and  $\gamma$  Dor type pulsation. On the other hand the hybrid stars occupy the same area in the Hertzsprung-Russell diagram as  $\delta$  Sct do and therefore a different stellar structure seems unreasonable.

The investigation of constant period spacings of the g modes of the  $\gamma$  Dor stars yields generally too low values of what is expected from theory. I find spacings that would require  $\ell > 3$  modes to explain my findings. Such modes, however, suffer from cancellation effects and are hardly detectable even by such a high precision photometer as CoRoT is. As a caveat I mention that based on my data no mode identification can be done which leaves the possibility that modes of different  $\ell$  mimic a constant period spacing.

To explore a possible connection between the hybrid pulsation and chemical abundance patterns, a detailed abundance analysis was done for two stars. This analysis resulted in one hybrid and Am star, while the other hybrid does not show this kind of chemical peculiarity. Thus, there is no connection between the hybrid phenomenon and hybrid pulsation.

## Curriculum Vitae

Mag. Markus Hareter

### Education after school

October 1997 - April 1998 military service 1998 - 2001 study of computer sciences, University of technology Vienna 2001 - 2007 study of astronomy June 20, 2007 graduation in astronomy master thesis: MOST Guide Star reduction October 2007: start of PhD-Thesis, title “Investigation of  $\gamma$  Doradus -  $\delta$  Scuti hybrid stars based on high precision space photometry and complementary ground bases spectroscopy”.

### Scientific Work since March 2005

Work on the data reduction of space based data from the MOST satellite, focus on the guide star data. Abundance analysis of selected  $\gamma$  Doradus and  $\gamma$  Doradus -  $\delta$  Scuti hybrid stars. Current work on CoRoT LRA01 data on  $\gamma$  Doradus and  $\gamma$  Doradus -  $\delta$  Scuti hybrid stars, frequency analyses and fundamental parameters from classification spectra.

### Meetings and Conferences

December 2005: MOST Science Team Meeting, Vienna (Talk)  
December 2006: MOST Science Team Meeting, Montreal (Talk)  
July 2007: MOST Science Team Meeting, Vancouver (Talk)  
July 2007: Conference New Challenges in Pulsating Stars, Vancouver (Poster)  
May 2008: Workshop on Doradus stars observed by CoRoT, Nice (Talk)  
June 2008: MOST Science Team Meeting, Vienna (Talk)  
June 2008: BRITE Workshop, Vienna (Talk)  
June 2011: 2nd CoRoT Symposium, Marseille, (Poster)  
December 2011: MOST Science Team Meeting Vienna  
May 2012: ESF Conference, Obergurgl, Austria (Talk)  
December 2012: MOST Science Team Meeting Vienna

### Schools

March 2011, EURO-VO ICE, Strasbourg

### Observing Runs

May 2008: SAAO, Sutherland, South Africa, 0.5-m Telescope  
December 2009: ESO, La Silla, Chile, 3.6-m Telescope, HARPS  
July 2011: ESO, La Silla, Chile, 3.6-m Telescope, HARPS

### Employments

April 2005 - September 2005: marginal employment

---

October 2005 - October 2007: FWF research support  
November 2007 - August 2008: PhD-Position, IfA  
September 2009 - August 2010: half PhD-Position, IfA  
September 2010 - December 2012: PhD-Position, IfA  
since January 2013: Postdoc position at the Konkoly Observatory, Hungary
